$$\left\lfloor \frac{\lfloor n/a \rfloor}{b} \right\rfloor = \left\lfloor \frac{n}{ab} \right\rfloor$$

3 Probability & Expected Value

3.1 Basic Rules

$$P(\bar{A}) = 1 - P(A) \quad P(\text{at least one}) = 1 - P(\text{none})$$

$$P(\geq 1 \text{ success in } n \text{ trials}) = 1 - (1-p)^n$$

$$P(A \cup B) = P(A) + P(B) - P(A \cap B)$$

$$P(A | B) = \frac{P(A \cap B)}{P(B)} \quad P(A \cap B) = P(A)P(B | A)$$

Only when independent: $P(A \cap B) = P(A)P(B)$.

3.2 Bayes / Total Probability

For a partition $A_1, \dots, A_n$ of the sample space:

$$P(B) = \sum_i P(B | A_i) P(A_i)$$

$$P(A_i | B) = \frac{P(B | A_i) P(A_i)}{\sum_j P(B | A_j) P(A_j)}$$

3.3 Distributions

Binomial — k successes in n trials:

$$P(X = k) = \binom{n}{k} p^k (1-p)^{n-k}$$

$$E[X] = np \quad \text{Var}(X) = np(1-p)$$

Geometric — first success on trial k :

$$P(X = k) = (1-p)^{k-1} p \quad E[X] = \frac{1}{p}$$

Cost c per attempt $\Rightarrow E[\text{cost}] = c/p$.

Negative binomial — r -th success on trial n :

$$P(X = n) = \binom{n-1}{r-1} p^r (1-p)^{n-r} \quad E[X] = \frac{r}{p}$$

3.4 Expected Value

$$E[X] = \sum_x x P(X = x) \quad E[aX + b] = aE[X] + b$$

$$E[f(X)] = \sum_x f(x) P(X = x) \quad E[X^2] \neq (E[X])^2$$

Linearity — holds even when the X_i are dependent:

$$E\left[\sum_i X_i\right] = \sum_i E[X_i]$$

3.5 Indicators

$I_A = 1$ if A happens, else 0, so $E[I_A] = P(A)$. For $X = \sum_i I_i$:

$$E[X] = \sum_i P(A_i)$$

Expected number of valid pairs:

$$E[X] = \sum_{i < j} P((i, j) \text{ valid})$$

Expected distinct values over n draws:

$$E[\text{distinct}] = \sum_v [1 - (1 - p_v)^n]$$

Asked for an expected count? Reach for indicators plus linearity before building the whole distribution.

3.6 Variance

$$\text{Var}(X) = E[X^2] - (E[X])^2$$

$$\text{Var}(X + Y) = \text{Var}(X) + \text{Var}(Y) + 2 \text{Cov}(X, Y)$$

Independent $\Rightarrow \text{Var}(\sum_i X_i) = \sum_i \text{Var}(X_i)$. Variance needs that independence; linearity of E never does.

3.7 Expected-Value DP

From state s , move to t with probability p_t paying $c(s, t)$:

$$E[s] = \sum_t p_t (c(s, t) + E[t])$$

One operation per step:

$$E_i = 1 + \sum_j p_{ij} E_j$$

Self-loop — finish with probability p , else repeat, cost c each time:

$$E = pc + (1-p)(c + E) \implies E = \frac{c}{p}$$

Many states $\Rightarrow$ solve $Ax = b$ by Gaussian elimination.
